DIFFIE-HELLMAN KEY EXCHANGE

AIM:

To implement Diffie-Hellman key exchange using C.

ALGORITHM:

Step 1: Choose a large prime number P and a primitive root modulo (P), denoted as (G). Both parties agree on these values.

Step 2: Alice chooses a private key (a), while Bob chooses a private key (b). These private keys are kept secret.

Step 3: Alice calculates her public key (x) using ($x = G^a \bmod P$), and Bob calculates his public key (y) using ($y = G^b \bmod P$).

Step 4: Alice sends her public key (x) to Bob, and Bob sends his public key (y) to Alice.

Step 5: Using the received public keys, Alice computes the secret key (k_a) using ($k_a = y^a \bmod P$), and Bob computes the secret key (k_b) using ($k_b = x^b \bmod P$).

Step 6: Both Alice and Bob now have the same shared secret key.

Step 7: They can now communicate securely using the shared secret key for encryption and decryption.

Step 8: The security of the Diffie-Hellman Key Exchange relies on the difficulty of calculating discrete logarithms in finite fields.

PROGRAM:

```
#include <math.h>
#include <stdio.h>
long long int power(long long int a, long long int b, long long int P)
{
    if (b == 1)
        return a;
    else
        return (((long long int)pow(a, b)) % P);
}
```

```
}  
int main()  
{  
    long long int P, G, x, a, y, b, ka, kb;  
    P = 23;  
    printf("The value of P : %lld\n", P);  
    G = 9;  
    printf("The value of G : %lld\n\n", G);  
    a = 4;  
    printf("The private key a for Alice : %lld\n", a);  
    x = power(G, a, P);  
    b = 3;  
    printf("The private key b for Bob : %lld\n\n", b);  
    y = power(G, b, P);  
    ka = power(y, a, P);  
    kb = power(x, b, P);  
    printf("Secret key for the Alice is : %lld\n", ka);  
    printf("Secret Key for the Bob is : %lld\n", kb);  
    return 0;  
}
```

OUTPUT:

```
The value of P : 23  
The value of G : 9  
  
The private key a for Alice : 4  
The private key b for Bob : 3  
  
Secret key for the Alice is : 9  
Secret Key for the Bob is : 9
```

RESULT:
